

Product-likelihood limit: f solves $\prod_i (1 - f p_{\text{epoch}} C_i) = 0.05$, with C_i the per-system recovery at threshold P ; p_{epoch} is the epoch activity

probability -- independent Bernoulli activity across execution blocks, not the intra-track dwell fraction. p_{epoch} scales every C_i :

a low-activity population is bounded only where $p_{\text{epoch}} C_i$ can still exclude $f = 1$; as $p_{\text{epoch}} \rightarrow 0$ no bound exists

at any P . Curve (b) is the conditional model limit quoted in the text, illustrative rather than a prevalence bound.

This release's windows were processed nearest-first: the current sensitivity distribution is not representative of the completed sample.
