

Product-likelihood limit: f solves $\prod_i (1 - f D C_i) = 0.05$, with C_i the per-system recovery at threshold P and D the assumed duty cycle.

A duty cycle scales every C_i , so a low-duty-cycle population is bounded only where $D C_i$ stays large enough to exclude $f=1$;
as $D \rightarrow 0$ no bound exists at any P . Curve (b) is the primary result quoted in the text.
