

The chain that decides

reported
alongside

Drift-following visibility fit

*a position-and-epoch consistency check,
not a filter in the chain*

- 50 of 56 crossings fitted, 6 untested in 4 blocks
 - localised: 11 under the committed epoch, 40 under the adopted one
 - 30 of those are unattributed, where v4.02 reported none
 - clauses 2 and 3 reject 4 of the 44 reaching $\text{Re}/\sigma \geq 4$
 - 12 controls resolve a rank of $\sim 1/13$; $E[\text{max of 12}] = 1.63$
- a crossing is DEFINED by excess at this position and cell, so the fit confirms the search rather than testing it independently

nothing survives the chain; no crossing is carried forward
